What is quantile regression

Regression setting:

- y is our response or dependent variable
- $\mathbf{x}$ is a vector of covariates or independent variables

In **distributional regression** we want a good model for $p(y|\mathbf{x})$.

Model is $p_m\{y|\theta_1(\mathbf{x}), \ldots, \theta_q(\mathbf{x})\}$, where $\theta_1(\mathbf{x}), \ldots, \theta_q(\mathbf{x})$ are parameters.

In a Gaussian model, the mean and/or variance depend on the covariates

$$y|\mathbf{x} \sim N\{y|\mu = \theta_1(\mathbf{x}), \sigma^2 = \theta_2(\mathbf{x})\},$$

where $\mu = \mathbb{E}(y|\mathbf{x})$ and $\sigma^2 = \text{Var}(y|\mathbf{x})$.

What is quantile regression

Figure: Gaussian model with variable mean and variance.
In mgcv: `gam(list(y~s(x), ~s(x)), family=gaulss)`.

What is quantile regression

Lots of options for $p_m(y|\mathbf{x})$: binomial, gamma, Poisson, Tweedie...
We consider continuous (not discrete) y.

Let $F(y|\mathbf{x})$ be Prob$(Y \leq y|\mathbf{x})$.

The τ-th ($\tau \in (0,1)$) quantile is $\mu_\tau(\mathbf{x}) = F^{-1}(\tau|\mathbf{x})$.
What is quantile regression

Given $p_m(y|\mathbf{x})$ we can get the conditional quantiles $\mu_\tau(\mathbf{x})$.

What is quantile regression

Quantile regression estimates conditional quantiles $\mu_\tau(\mathbf{x})$ directly.

No model for $p(y|\mathbf{x})$.

What is quantile regression

The τ-th quantile is
$$\mu = F^{-1}(\tau|\mathbf{x}),$$
but also the minimizer of
$$L(\mu|\mathbf{x}) = \mathbb{E}\big\{ \ \rho_\tau(y - \mu)|\mathbf{x} \ \big\},$$
where
$$\rho_\tau(z) = (\tau - 1)z\mathbb{1}(z < 0) + \tau z\mathbb{1}(z \geq 0),$$
is the "pinball" loss.

What is quantile regression

In **linear quantile regression** $\mu_\tau(\mathbf{x}) = \boldsymbol{\beta}^\mathsf{T}\mathbf{x} = \beta_1 x_1 + \ldots \beta_p x_p$.

$\hat{\boldsymbol{\beta}}$ is the minimizer of total pinball loss

$$\hat{\boldsymbol{\beta}} = \operatorname*{argmin}_{\beta} L_y(\boldsymbol{\beta}) = \sum_{i=1}^{n} \rho_\tau(y_i - \boldsymbol{\beta}^\mathsf{T}\mathbf{x}_i).$$

In **additive quantile regression** $\mu_\tau(\mathbf{x}) = \sum_{j=1}^{m} f_j(\mathbf{x})$.

f_j's can be fixed, random or smooth effects.

$\hat{\boldsymbol{\beta}}$ is the minimizer of total **penalized** pinball loss

$$\hat{\boldsymbol{\beta}} = \operatorname*{argmin}_{\beta} \big\{ L_y(\boldsymbol{\beta}) + \operatorname{Pen}(\boldsymbol{\beta}) \big\}.$$

where $\operatorname{Pen}(\boldsymbol{\beta})$ penalizes the complexity of the f_j's.

Structure of the talk

Structure:

1. What is quantile regression
2. **When is it useful**
3. How to do quantile regression using `qgam`

When is quantile regression useful

Median income is a better indicator of how the "average" person is doing, relative to mean income.
# When is quantile regression useful

The median is also more **resistant to outliers**.
When is quantile regression useful

Some quantiles are more important than others:

- electricity producers need to satisfy top electricity demand
- urban planners need estimates of extreme rainfall

When is quantile regression useful

Effect of explanatory variables may depend on quantile
When is quantile regression useful

$$q_\tau(\text{Demand}) = f_1(\text{Temp}) + f_2(\text{TimeOfYear}) + f_3(\text{Trend}) + f_4(\text{Holiday}) + \cdots$$

When is quantile regression useful

$q_\tau(\text{RT}) = f_1(\text{Subject}) + f_2(\text{Trial}) + f_3(\text{WordFrequency}) + f_4(\text{WordLength}) + \cdots$
When is quantile regression useful

No assumptions on $p(y|\mathbf{x})$:

- no need to find good model for $p(y|\mathbf{x})$;
- no need to find normalizing transformations (e.g. Box-Cox);

## Structure:

1. What is quantile regression?
2. When is it useful
3. **Quantile regression using qgam**

Smoothing the pinball loss

`qgam` uses a modified loss which we call Extended log-F (ELF) loss.

This is smooth and convex and, as $\lambda \to 0$, we have recover pinball loss.

NB in qgam, λ reparametrized as `err` $\in (0, 1)$ ($\downarrow$ `err` implies $\downarrow \lambda$).

Smoothing the pinball loss

Increasing `err` leads to:

- faster and more stable computation
- more bias

Interpretation, if μ^* is minimizer of ELF loss:

$$|F(\mu^*) - \tau| \leq \text{err}$$

`err` is an upper bound on the bias.

By default:

```
qgam(..., err = 0.05, ...)
```

Residual checking

We have no model for $p(y|\mathbf{x}) \rightarrow$ QQ-plots are useless.

We can check the proportion of residuals < 0, which should be $\approx \tau$.

```
check1D(b, "x") + l_gridQCheck1D(qu = 0.5)
```

Model selection

In probabilistic regression we can use Akaike Information Criterion (AIC):

$$\text{AIC} = \underbrace{-2 \log p(\mathbf{y}|\boldsymbol{\beta})}_{\text{goodness of fit}} + \underbrace{2p}_{\text{model complexity}}$$

If $\text{AIC}_{m1} < \text{AIC}_{m2}$ choose model 1.

In quantile regression pinball loss substitutes likelihood $\log p(\mathbf{y}|\boldsymbol{\beta})$.

Maybe justifiable for median regression ($\tau = 0.5$).

Practical approach: choose model with lowest AIC at median and use it for other quantiles.

Probably better: choose model on mean model and use it for quant reg.

THANK YOU!
